## What is computational geometry?

- CG implements real world geometry with rich algorithmic structures and machine arithmetic.
- Simulations, construction, geometric computations / measurement, help in decision.
- Applications: computer graphics, terrain simulation, geography / environment, telephone technology...

## Outline

- 1 Introduction
  - A real story
  - Point query
  - Nearest neighbour interpolation
  - General position assumption
- 2 Voronoi diagram
  - Definitions
  - A few examples
  - Fundamental properties
  - Construction
- 3 Delaunay triangulation
  - Definitions
  - Properties
  - Construction
  - Location
  - Extras...

## Lost in the Alps (c. 2000)

- Three friends on a winter mountain hike in the Alps.
- Storm gathered. Got caught in blizzard.
- They had a cellular telephone with a weak battery. Made a **desperate** call to friend, battery expired, friend called rescue team, who called the police.
- The telephone company finally managed to **locate** them. All got rescued (safe), after three long (and *costly*) days of suspense.

## Mathematical formulation

- Data:
  - Let  $S_n = \{s_1, s_2, \dots, s_n\}$  be a “cloud” of  $n$  distinct points (called **sites**<sup>1</sup>) in the Euclidean plane  $E^2$ .
  - Let  $q$  be *any* point in  $E^2$ .
- Question: What is the site “closest” to  $q$  in  $S_n$ ?  
i.e., find (possibly *not unique*)  $j \in [1, n]$  such that:

$$d(q, s_j) \leq d(q, s_i) \forall i \in [1, n].$$

<sup>1</sup>Here: telephone relays

## Example (Delaunay mesh)

## Example (query and nearest site)

## Final location – geometrical approach

Distances from cell phone to three nearest relays allow computing actual location of phone call.

## Final location – analytical approach

$$q \in \Gamma(A, r_A) \Leftrightarrow (x_q - x_A)^2 + (y_q - y_A)^2 = r_A^2 \quad (1)$$

$$q \in \Gamma(B, r_B) \Leftrightarrow (x_q - x_B)^2 + (y_q - y_B)^2 = r_B^2 \quad (2)$$

$$q \in \Gamma(C, r_C) \Leftrightarrow (x_q - x_C)^2 + (y_q - y_C)^2 = r_C^2 \quad (3)$$

Subtract (2) from (1) and (3) from (2) and divide by 2 :

$$x_q(x_B - x_A) + y_q(y_B - y_A) = (r_A^2 - x_A^2 - y_A^2 - (r_B^2 - x_B^2 - y_B^2))/2$$

$$x_q(x_C - x_B) + y_q(y_C - y_B) = (r_B^2 - x_B^2 - y_B^2 - (r_C^2 - x_C^2 - y_C^2))/2$$

Determinant of system on two unknowns  $(x_q, y_q)$ :

$$\Delta = \begin{vmatrix} x_B - x_A & y_B - y_A \\ x_C - x_B & y_C - y_B \end{vmatrix} \equiv \begin{vmatrix} 1 & 1 & 1 \\ x_A & x_B & x_C \\ y_A & y_B & y_C \end{vmatrix},$$

null if and only if  $A, B$ , and  $C$  are **collinear**.

## Geographical instantiation: altitudes

$$\begin{aligned} z_q &= (z_\gamma - z_\alpha) \times \overline{\alpha q} / \overline{\alpha \gamma} \\ &= ((z_B - z_A) \cdot \overline{A\gamma} / \overline{AB} - (z_B - z_C) \cdot \overline{C\alpha} / \overline{CB}) \cdot \overline{\alpha q} / \overline{\alpha \gamma} \end{aligned}$$

## General setting

- A frequent requirement in geo-sciences, but also in other domains (Gouraud shading, etc.)
- Find the value of a given **function** at a given query point  $q$  by interpolating those known at three “sites” surrounding it, say  $A, B, C$ .
- Strong constraint: the triangle  $ABC$  **must not** contain any other “site” in its strict interior.

## Limiting special cases

In all these cases, we want to find the site nearest to one query point  $q$ , but special cases may arise:

- $q$  coincides with one site.
- $q$  is closest to two (or more!) sites:  $\exists u, v \in [1, n]^2$  such that  $d(q, s_u) = d(q, s_v) \leq d(q, s_i) \forall i \in [1, n]$ .
- All sites are aligned, and  $q$  lies outside supporting line...
- **General position assumption:**
  - 1 no more than two sites are aligned;
  - 2 no more than three sites are co-circular (except if their circumcircle is not empty).

## Bisector

- We shall only concentrate on 2-D. Almost all definitions generalize to any dimensions.
- Let  $S_n = \{s_1, s_2, \dots, s_n\}$  be a set of  $n$  sites in general position in  $\mathbb{E}^2$ .  
Site  $s_i$  will be abbreviated to  $i$  whenever no confusion is possible.
- Let  $(i, j) \in [1, n]^2$ ,  $i \neq j$ .  $B_{ij} = \{p \in \mathbb{E}^2 \mid d(p, s_i) = d(p, s_j)\}$  is called the **bisector** of sites  $i$  and  $j$ .  
**Note:**  $B_{ij} \equiv B_{ji} \forall i, j$ .
- Let  $H_{ij}(H_{ji})$  be the half-plane delimited by and including  $B_{ij}$ , and containing  $s_i(s_j)$ .  
**Note:**  $H_{ij} \cup H_{ji} = \mathbb{E}^2$ ,  $H_{ij} \cap H_{ji} = B_{ij}$ .

## Voronoi polygon – definition

Let  $i \in [1, n]$ , and  $s_i$  be the corresponding site of  $S_n$ :

- $\mathcal{PV}(i) = \cap_{j \in [1, n] - \{i\}} H_{ij}$ .
- $\mathcal{PV}(i) = \{z \in \mathbb{E}^2 \mid d(z, s_i) \leq d(z, s_j) \forall j \in [1, n]\}$ .
- All the sites of  $S_n - \{s_i\}$  that contribute a bisector with  $s_i$  are generically called the **nearest neighbours** of  $s_i$ .

## Bisector – illustration

## Voronoi polygon – illustration

## Voronoi polygon – properties

- $s_i \in \mathcal{PV}(i) \implies \mathcal{PV}(i) \neq \emptyset$ .
- $\mathcal{PV}(i)$  is convex.
- $\mathcal{PV}(i)$  is unbounded if and only if  $s_i$  lies on the boundary of the convex hull of  $S_n$ .
- The intersection of the Voronoi polygons of any two distinct sites  $s_i$  and  $s_j$  is either empty or contains a (possible infinite) section of  $B_{ij}$ .
- The intersection of the Voronoi polygons of three distinct sites of  $S_n$  is either empty or reduced to a single **Voronoi vertex** (the center of the circumcircle through these sites).
- Due to the general position assumption, the degree of all Voronoi vertices is exactly three.

## Voronoi diagram – illustration

## Voronoi diagram – definition

- The Voronoi diagram of  $S_n$  is the union of all the Voronoi polygons on the sites  $s_i$ ,  $i \in [1, n]$ .
- $\mathcal{V}(S_n) = \bigcup_{i \in [1, n]} \mathcal{PV}(i)$ .
- It is a graph whose edges are segments of bisectors on  $S_n^2$ , and whose vertices (**Voronoi vertices**) are the centers of circles circumscribed to triples of sites of  $S_n$ .

## Voronoi diagram – omnipresence in nature (1/2)

## Voronoi diagram – omnipresence in nature (2/2)

## Empty disk property

### Theorem

Let  $s_i, s_j, s_k$  be three sites of  $S_n$  such that  $\mathcal{PV}(i) \cap \mathcal{PV}(j) \cap \mathcal{PV}(k) = \{\gamma\}$ .

The disk centered in  $\gamma$  through  $s_i, s_j$  and  $s_k$  has no other site in its interior.

## Voronoi diagram – even in image analysis...

The notion of **skiz** (skeleton by influence zone)... also known as **water shed**, dividing line, or great divide.

## Empty disk property – illustration

## Empty disk property – proof

- Let  $s_i, s_j, s_k$  s.t.  $\mathcal{PV}(i) \cap \mathcal{PV}(j) \cap \mathcal{PV}(k) = \{\gamma\}$ .
- $\Gamma(i, j, k)$  circle through  $s_i, s_j, s_k$  with center  $\gamma$ , radius  $r = d(\gamma, s_i) = d(\gamma, s_j) = d(\gamma, s_k)$ .
- Suppose  $\Gamma(i, j, k)$  contains a certain site  $s_\ell$  in its interior. Now  $\ell$  is necessarily closer to one of the three sites, say  $s_k \implies \ell \in \mathcal{PV}(k)$ .
- Then  $d(\gamma, \ell) < r \implies \gamma \in \mathcal{PV}(\ell)$ , and not  $\mathcal{PV}(i) \cap \mathcal{PV}(j) \cap \mathcal{PV}(k)$ , a **contradiction**.
- Hence  $\text{int}(\Gamma(i, j, k))$  is **necessarily empty**.

## Divide-and-conquer algorithm (principle) – optimal

To build the Voronoi diagram of  $S$ , with size  $n \geq 3$  (else, build it 'by hand'):

- **Divide step:** Split  $S$  into two "equal", linearly separable subsets  $B, R$  (blue and red / left and right)

$$(B \cap R = \emptyset, B \cup R = S_n, |B| = \lfloor n/2 \rfloor, |R| = n - \lfloor n/2 \rfloor)$$

$$\forall b \in B, r \in R, b <_{xy} r).$$

- Recurse on  $B$  and  $R$  to construct Voronoi diagrams  $\mathcal{VD}(B), \mathcal{VD}(R)$ .
- **Merge step:** Follow **dividing line** at equal distance from one vertex in  $B$  and one vertex in  $R$ , clipping all edges of  $\mathcal{VD}(B)$  that overlap on  $\mathcal{VD}(R)$ , and conversely.
- Complexity:  $O(n \log n)$  (optimal).

## Complexity

### Theorem

Let  $S_n$  contain  $n$  distinct sites of  $\mathbb{E}^2$ . It takes  $\Omega(n \log n)$  time to construct the Voronoi diagram of  $S_n$  ( $\mathcal{VD}(S_n)$ ).

- Proof:
  - Recall fact: Sorting  $n$  real numbers by comparison takes  $\Theta(n \log n)$  (optimal) time.
  - Suppose we choose  $n$  sites in random order on a line.
  - Build  $\mathcal{VD}(S_n)$  in alleged  $o(n \log n)$  time.
  - $\mathcal{VD}(S_n) \rightsquigarrow n - 1$  parallel lines in increasing order.
  - Hence  $\mathcal{VD}(S_n) \rightsquigarrow S_n$  sorted in less than optimal time. A contradiction.

## Building $\mathcal{VD}(S)$ divide step + recursion

## Building $\mathcal{VD}(S)$ merge step

## Voronoi diagram – a summary

- Although a powerful structure, the Voronoi diagram does not yield a direct answer to the original question : "Which site is nearest to a given query point?"
- To locate the nearest site, we still need to scan all the Voronoi polygons.
- Each search takes optimal  $O(\log n)$  time (binary search on convex polygons of size  $O(n)$ ), but there are  $O(n)$  such polygons!
- Construction time:  $O(n \log n)$ . Query time:  $O(n) + O(\log n) = O(n)$ .
- We need another structure to help us...

## Building $\mathcal{VD}(S)$ after merge

## Duality

Define the following procedure:

- Connect all couples of sites in  $S_n$  whose bisector contributes to  $\mathcal{VD}(S_n)$  by a non-null segment.
- The resulting graph is the **dual** graph of  $\mathcal{VD}(S_n)$ .
- In 1932, B. Delaunay showed that this graph is a triangulation.
- This graph is called the **Delaunay triangulation** of  $S_n$ .
- By definition, it may be deduced from  $\mathcal{VD}(S_n)$  in linear ( $O(n)$ ) time.

## Delaunay triangulation – an illustration

## Delaunay triangulation – an illustration

## Delaunay triangulation – an illustration

## As deduced from $\mathcal{VD}(S_n)$

- The vertices of  $\mathcal{DT}(S_n)$  are the sites.
- Its edges are called **Delaunay edges**, and connect two sites of  $S_n$ .
- The edges of  $\text{conv}(S_n)$  are all Delaunay edges.
- The orthocenter of each Delaunay triangle is a Voronoi vertex of  $\mathcal{VD}(S_n)$ .
- The circumdisk of triangle  $\triangle(s_i, s_j, s_k)$  in  $\mathcal{DT}(S_n)$  has no site in its interior.

## Counting elements a triangulation – definition

- A graph  $\mathcal{G}(V, E)$  is said to be **connected** if any pair of vertices of  $V$  may be linked with (at least) one path (series of edges in  $E$ ).
- A segment-based graph  $\mathcal{G}(V, E)$  is said to be **planar** if any two edges in  $E$  either are disjoint or share *exactly one* endpoint.
- In a planar graph, a **face** is a cycle (closed path) with no other edge in its interior.
- The **external** face of a connected planar set is its unbounded face.

## Counting elements in a triangulation – Euler's relation

### Theorem (L. Euler)

Let  $\mathcal{G}(V, E)$  be a planar, connected graph, with  $f, e, v$  denoting its number of faces, edges and vertices. Then

$$v - e + f = 2.$$

## Connected planar graph – an illustration

## Counting elements in a triangulation – shooting arrows

Let  $T$  be any triangulation in the plane (including  $DT(S_n)$ ), with  $t$  triangles,  $n$  vertices and  $e$  edges.

Let  $x$  be the number of edges on the boundary of its external face  $X$ :

- Draw an arrow on both sides of each edge.
- There are two arrows per edge, i.e.,  $2e$  arrows.
- There are three arrows per triangle, i.e.,  $3t$  **internal** arrows.
- There is one outgoing arrow per external face edge, i.e.,  $x$  **external** arrows.

## Counting elements in a triangulation – linearity

- Summary:

$$\begin{aligned} f &= t + 1, \\ 2e &= 3t, \\ n - e + t &= 1 \quad (\text{Euler's relation}). \end{aligned}$$

- This yields:

$$\begin{aligned} t &= 2(n - 1) - x, \\ e &= 3(n - 1) - x. \end{aligned}$$

- Since  $3 \leq x \leq n$ :

$$\begin{aligned} n - 2 &\leq t \leq 2n - 5, \\ 2n - 3 &\leq e \leq 3n - 6. \end{aligned}$$

- The size of  $\mathcal{DT}(S_n)$  (and hence  $\mathcal{VD}(S_n)$ ) is linear.

## Four circular points – an illustration

## Empty disk – max min angle equivalence

- Let  $A, B, C, D$  be 4 co-circular points, in that order.
- Polygon  $Q = (A, B, C, D)$  is convex. Let  $AB$  be its smallest edge (w.l.g).
- Then  $\angle ADB = \angle ACB$  are the smallest of the 12 angles of the two possible triangulations for  $Q$ .

## Empty disk – max min angle equivalence

- Let  $D$  move infinitesimally inside circle.
  - $\angle ACB$  remains constant, while  $\angle AD'B' > \angle ADB$ .
  - Disk through  $A, B, C$  contains  $D$  in its interior.

## Move $D$ inside – an illustration

## Diagonal “flip” – an illustration

## Empty disk – max min angle equivalence

- The empty disk criterion selects diagonal  $BD$ .
- Maximizing the minimum angle selects diagonal  $BD$ .
- $\rightsquigarrow$  The two criteria (empty disk and maximize minimum angle) are equivalent.
- This gives one constructing method, with two selection equivalent criteria:
  - Start with any triangulation on  $S_n$ .
  - While it contains at least one triangle with non-empty circumscribed disk, “flip” diagonals.

## Incremental insertion quadratic running time

## Incremental insertion quadratic running time

## Incremental insertion quadratic running time

## Incremental insertion quadratic running time

## Divide-and-conquer algorithm (principle) – optimal

To build the Delaunay triangulation of  $S$ , with size  $n \leq 3$  (else: build it "by hand"):

- **Divide step:** Split  $S$  into two "equal", linearly separable subsets  $B, R$  (blue and red / left and right)  
 $(B \cap R = \emptyset, B \cup R = S_n, |B| = \lfloor n/2 \rfloor, |R| = n - \lfloor n/2 \rfloor)$   
 $\forall b \in B, r \in R, b <_{xy} r$ .
- Recurse on  $B$  and  $R$  to construct Delaunay triangulations  $DT(B), DT(R)$ .
- **Merge step:** Remove all triangles in  $DT(B)$  whose circumdisk contains a site in  $R$ ; remove all triangles in  $DT(R)$  whose circumdisk contains a site in  $B$ . Fill the "gap" between the two resultant graphs by edges with one vertex in  $B$  and the other in  $R$ .
- Complexity:  $O(n \log n)$  (optimal).

## Building $DT(S)$ divide step + recursion

## Building $DT(S)$ merge step : remove conflicting triangles

## Building $DT(S)$ merge step : rebuild

## Building $DT(S)$ after merge

## A brute-force solution

- For each triangle  $t$  in  $\mathcal{DT}(S_n)$ :
  - If  $t$  contains  $q$ : stop
  - Else:  $t \leftarrow \text{succ}(t)$ .
- Complexity:  $O(2n - 5) = O(n)$ .

## Jump and walk – an illustration

## A finer solution – Jump and walk

- If  $q$  lies outside  $\text{conv}(S_n)$ : stop ( $O(\log n)$  time).
- Else: pick up a random site  $s$  in  $S_n$ .
- Find triangle  $t$  around  $s$  containing segment  $[sq]$ .
- **Walk**: until end of time
  - If  $t$  contains  $q$ : stop
  - Else:  $t \leftarrow \text{adj}(t)$  % walk to adjacent triangle crossing  $(sq)$ .
- Complexity: if the sites are **uniformly distributed**,  $O(\sqrt{n})$  on average. [Sibson & Green – proof : Devroye].

## Refined Jump and walk

- If  $q$  lies outside  $\text{conv}(S_n)$ : stop ( $O(\log n)$  time).
- Else: pick up  $k \in [1, n]$  random sites  $S_n$ .
- Let  $s$  be the site among those closest to  $q$ .
- Find triangle  $t$  around  $s$  containing segment  $[sq]$ .
- **Walk**: until end of time:
  - If  $t$  contains  $q$ : stop
  - Else:  $t \leftarrow \text{adj}(t)$  % walk to adjacent triangle crossing  $(sq)$ .
- Complexity: if the sites are **uniformly distributed**,  $O(k + \sqrt{n/k})$  on average. Optimal  $O(\sqrt[3]{n})$  reached for  $k = \Theta(\sqrt[3]{n})$  [Devroye, Zhu].

## Binsearch and walk

- If  $q$  lies outside  $\text{conv}(S_n)$ : stop ( $O(\log n)$  time).
- Else: maintain a balanced tree on  $xy$  order.
- Search for  $q$  in tree and stop when there are  $O(k)$  elements in remaining subtree.
- Traverse entire subtree and determine site  $s$  closest to  $q$ .
- Find triangle  $t$  around  $s$  containing segment  $[sq]$ .
- **Walk**: until end of time
  - If  $t$  contains  $q$ : stop
  - Else:  $t \leftarrow \text{adj}(t) \% \text{walk to adjacent triangle crossing } (sq)$ .
- Complexity: if the sites are **uniformly distributed**,  $O(k + \sqrt{n}/k)$  on average. Optimal  $O(\sqrt[4]{n})$  reached for  $k = \sqrt[4]{n}$ . [Devroye, Lemaire, Moreau, 2004].

## Binsearch and walk – an illustration (1/4)

## Binsearch and walk – an illustration (1/4)

## Binsearch and walk – an illustration (3/4)

## Binsearch and walk – an illustration (4/4)

## Constrained adaptive DT (2/2) – illustration

## Constrained adaptive DT (1/2)

- The data set may be a graph, with **constrained** edges: edges that may not be crossed by any element of the resulting Delaunay triangulation.
  - $\rightsquigarrow$  modify the definition so it allows circumdisks to contain sites that **not visible** from all three triangle vertices at the same time. Divide-and-conquer becomes much more difficult (JMM 1993).
- The density of the sites may vary with specific parameters. For instance with  $\sqrt{h}$ , for bathymetric data.
  - $\rightsquigarrow$  apply locally perturbed distribution functionals.

## Terrain simulation

- Given: a large number of terrain data  $(x, y, z$  in 2-D).
- Wanted: a mesh with minimum number of facets and maximum “**goodness of fit**”.
- Method:
  - 1 Start with initial square (or triangle) covering all data; triangulate with initial diagonal; assign each data point to appropriate triangle.
  - 2 Repeat until **gof** reached or all points processed:
    - 1 Find triangle  $t$  containing point  $p$  with maximum vertical deflection.
    - 2 Destroy  $t$  and replace with 3 new triangles sharing  $p$ .
    - 3 Redistribute points in  $t$  to 3 new triangles.
    - 4 Reinstaurate Delaunay property and redistribute as needed.

## Robustness issues

- Geometry with **doubles** is very different from **real** geometry.
- Example: Let  $\Omega$  be the intersection of **integral** lines  $AB$  and  $CD$ . Check that  $\Omega \in AB$  or  $CD$  is next to impossible, due to real number representation in machine.
- One good solution: **lazy arithmetic**. See explanations on blackboard...
